

§ 3.8 Exponential Growth & Decay

Ex $y = \# \text{ people world wide who have been infected w/ novel coronavirus (COVID-19)}$

listen to news: yesterday 1000 new infections

$$\left. \frac{dy}{dt} \right|_{t=60} = 1000 \quad \text{for } t = \text{days since 1 december}$$

What is $\frac{dy}{dt}$?

$$\frac{dy}{dt} = 10$$

$$y = 10t$$

$t = \text{days}$

$$\frac{dy}{dt} = 8t$$

$$y = 4t^2$$

$$\frac{dy}{dt} = 8y$$

$$y = e^{8t}$$

$$y' = e^{8t} \cdot 8 = 8y$$

In general: $\frac{dy}{dt} = ky$

$$\text{then } y = C e^{kt} = y(0) \cdot e^{kt}$$

↑ initial population

Ex Bacteria

- growth is proportional to size of pop.
- start w/ 20 cells
- 2 hours later 100 cells.

→ write expression for population as a fcn. of time

$$P = P_0 e^{kt}$$

$$P = 20 e^{kt}$$

$$100 = 20 e^{k \cdot 2}$$

$$\begin{aligned} 5 &= e^{2k} \\ \ln 5 &= 2k \\ k &= \frac{1}{2} \ln 5 \end{aligned}$$

$$\frac{1000}{20} = e^{\frac{\ln 5}{2} t}$$

$$\frac{2 \cdot \ln 50}{\ln 5} = t \approx 4.8614$$

$$\text{ANS: } P(t) = 20 e^{\frac{\ln 5}{2} t}$$

- Find + interpret $P'(3)$ + $P(3)$
- When does pop reach 1000?

$$P(3) = 223.6 \quad \leftarrow \text{units bacteria}$$

$$P'(t) = \frac{20 \cdot \ln 5}{2} e^{\frac{\ln 5}{2} t}$$

$$P'(3) = 10 \ln 5 e^{\frac{3}{2} \ln 5} = 179.9 \text{ bacteria/hour}$$
